Title:

DBMS for Healthcare Assistance Program Finder

Description:

I propose developing a web-enabled database system to help individuals find healthcare-related financial assistance programs. The idea comes from my current internship, where I work with healthcare data and analyze financial burden. Through this experience, I noticed that many people struggle to find and access available support programs.

Information about assistance programs, such as medication support or hospital bill relief, is often scattered and difficult to navigate. This system will centralize that information in a structured database and make it easier to search and use.

Users will be able to enter basic information such as ZIP code, income level, insurance type, and healthcare expenses. Based on this, the system will help identify relevant assistance programs and organizations. A simple web interface will allow users to search, and administrators to manage and update the data.

Scope:

The system will use a relational database to store and organize data related to patients, healthcare expenses, insurance, and assistance programs.

It will include:

- Patient information (ZIP code, income level, basic details)
- Insurance data
- Healthcare expenses
- Assistance programs and eligibility criteria
- Organizations providing support
- Geographic information for matching users with nearby resources
- Basic records of user requests and program matches

The system will allow users to input their information and find relevant assistance programs. It will also support basic reporting and data management.

The project will focus on storing and querying data for matching users with programs. It will not include real-time integration with external systems or advanced automation.
